

On the generalized convex functions  
with respect to the three-parameters family  
of functions

1. INTRODUCTION

M.C. Peixoto gave in his paper [8] the definition of generalized convex function with respect to a three-parameters family of functions and proved that a function

$\psi \in C^3(a,b)$  is a generalized convex function with respect to the family of solutions of the equation  $y''' = f(x,y,y',y'')$ , if and only if it satisfies the inequality  $\psi'''(x) \gg f(x,\psi(x),\psi'(x),\psi''(x))$ .

In this paper we shall give some equivalent conditions for a two times differentiable function to be a generalized convex function with respect to a three-parameters family of functions of class  $C^2$ .

Similar results for the generalized convexity with respect to a two-parameters family of functions may be found in the papers [1], [2], [3], [5], [6] and [9].

## 2. SOME EQUIVALENT CONDITIONS OF CONVEXITY

We shall assume the following hypothesis:

H. Let  $F$  be a three-parameter family of functions defined in an open interval  $I = (a, b)$  and satisfying the following conditions:

(i) every function  $\varphi \in F$  belongs to  $C^2(I)$ ;

(ii) for every  $x_0 \in I$  and for every  $y_0, y_1, y_2 \in \mathbb{R}$  there is a unique member  $\varphi$  of the family  $F$  such that

$$\varphi^{(i)}(x_0) = y_i, \quad i = 0, 1, 2;$$

(iii) for every three points  $(x_1, y_1), (x_2, y_2), (x_3, y_3)$ ,  $a < x_1 < x_2 < x_3 < b$  there is a unique member  $\varphi$  of the family  $F$  such that

$$\varphi(x_i) = y_i, \quad i = 1, 2, 3.$$

DEFINITION. Let hypothesis H be fulfilled. The function  $\psi$  is said to be strictly convex with respect to the family  $F$  iff for all  $x_1, x_2, x_3$  such that  $a < x_1 < x_2 < x_3 < b$  the inequalities

$$\psi(x) > \varphi(x) \quad \text{for } x \in (x_1, x_2)$$

$$\psi(x) < \varphi(x) \quad \text{for } x \in (x_2, x_3)$$

hold, where  $\varphi \in F$  is determined by the conditions

$$(1) \quad \varphi(x_i) = \psi(x_i) \quad i = 1, 2, 3.$$

We say that  $\psi$  is convex with respect to  $F$  iff it satisfies weak inequalities ( $\leq$ ) instead of the strong ones.

Similarly we define a strictly concave (concave) function with respect to  $F$  by reversing the inequalities.

**R e m a r k 1.** (see [8]) If a function  $\psi$  is strictly convex with respect to  $F$  then for all  $x_1, x_2, x_3$  such that  $a < x_1 < x_2 < x_3 < b$  the inequalities

$$\psi(x) < \varphi(x) \quad \text{for } x \in (a, x_1)$$

$$\psi(x) > \varphi(x) \quad \text{for } x \in (x_3, b)$$

hold, where  $\varphi \in F$  is determined by the conditions (1).

**THEOREM.** Let hypothesis  $H$  be fulfilled and let a function  $\psi : I \rightarrow R$  be twice differentiable in  $I$ . Under these assumptions the following statements are equivalent:

(A) the function  $\psi$  is strictly convex with respect to the family  $F$ ;

(B) for every  $x_1, x_2$ , such that  $a < x_1 < x_2 < b$  the inequalities

$$\psi(x) < \varphi(x) \quad \text{for } x \in (a, x_1),$$

$$\psi(x) > \varphi(x) \quad \text{for } x \in (x_1, b) \setminus \{x_2\}$$

hold, where  $\varphi \in F$  is determined by the conditions

$$(2) \quad \varphi(x_1) = \psi(x_1), \quad \varphi(x_2) = \psi(x_2), \quad \varphi'(x_2) = \psi'(x_2);$$

(C) for every  $x_0 \in (a, b)$  the inequalities

$$\psi(x) < \varphi(x) \quad \text{for } x \in (a, x_0)$$

$$\psi(x) > \varphi(x) \quad \text{for } x \in (x_0, b)$$

hold, where  $\varphi \in F$  is determined by the conditions

$$(3) \quad \varphi^{(i)}(x_0) = \psi^{(i)}(x_0) \quad i = 0, 1, 2;$$

(D) for every  $x_1, x_2$ , such that  $a < x_1 < x_2 < b$  the inequalities

$$\psi(x) < \varphi(x) \quad \text{for } x \in (a, x_2) \setminus \{x_1\}.$$

$$\psi(x) > \varphi(x) \quad \text{for } x \in (x_2, b)$$

hold, where  $\varphi \in F$  is determined by the conditions

$$(4) \quad \varphi(x_1) = \psi(x_1), \quad \varphi'(x_1) = \psi'(x_1), \quad \varphi(x_2) = \psi(x_2).$$

First we shall give some lemmas needed in the proof of the theorem.

**LEMMA 1.** (see [4], c.f. [7]) Let  $F \subset C^2(I)$ , where  $I$  is an open interval, be a three-parameter family of functions and the initial value problem (see H(ii)), as well as the boundary value problem (see H(iii)) are uniquely solvable in  $F$ . Then

(M1) for every  $x_1, x_2, y_0, y_1, y_2 \in R$ , such that  $a < x_1 < x_2 < b$  there is a unique member  $\varphi$  of  $F$  such that

$$\varphi(x_1) = y_1, \quad \varphi'(x_1) = y_0, \quad \varphi(x_2) = y_2;$$

(M2) for every  $x_1, x_2, y_0, y_1, y_2 \in R$ , such that  $a < x_1 < x_2 < b$  there is a unique member  $\varphi$  of  $F$  such that

$$\varphi(x_1) = y_1, \quad \varphi(x_2) = y_2, \quad \varphi'(x_2) = y_0$$

(i.e. the mixed problems are also uniquely solvable in  $F$ ).

The uniqueness of the functions  $\varphi$  determined by the conditions (2) and (4) follows from the above Lemma.

**LEMMA 2.** (see [8]) Let  $a < x_1 < x_2 < b$  and  $\varphi_1$  and  $\varphi_2$  be two elements of the family  $F$  such that  $\varphi_1 \neq \varphi_2$  and  $\varphi_1(x_1) = \varphi_2(x_1)$   $i = 1, 2$ .

Then  $\varphi_1(x) > \varphi_2(x)$  for  $x \in (x_1, x_2)$  and  $\varphi_1(x) < \varphi_2(x)$  for  $x \in (a, x_1) \cup (x_2, b)$  (or the reverse inequalities hold).

LEMMA 3. Let functions  $f, g$  be defined and two times differentiable in a neighbourhood of a point  $x_0$  and let  $f(x_0) = g(x_0)$ . Then

- a) if  $f(x) \gg g(x)$  for  $x \neq x_0$ , then  $f'(x_0) = g'(x_0)$ ;  
 b) if  $f(x) \gg g(x)$  for  $x > x_0$  (or for  $x < x_0$ ) and  $f'(x_0) = g'(x_0)$ , then  $f''(x_0) \gg g''(x_0)$ ;  
 c) if  $f(x) \gg g(x) \gg 0$  for  $x > x_0$  (or for  $x < x_0$ ) and  $f(x_0) = f'(x_0) = f''(x_0) = 0$ , then  $g'(x_0) = g''(x_0) = 0$ .

P r o o f. Part a) is obvious.

We shall prove b) for  $x > x_0$ . For  $x < x_0$  the proof is similar. Let us consider the function  $h(x) = f(x) - g(x)$ . From the assumptions we have  $h(x_0) = 0$ ,  $h'(x_0) = 0$  and  $h(x) \gg 0$  for  $x > x_0$ . Hence it follows that there exists a sequence  $\{x_n\}$  such that  $x_n \rightarrow x_0^+$  and  $h'(x_n) \gg 0$ . Therefore  $h''(x_0) \gg 0$ , thus  $f''(x_0) \gg g''(x_0)$ .

Part c). From a) we get  $g'(x_0) = 0$ , from b)  $f''(x_0) \gg g''(x_0)$  and  $g''(x_0) \gg 0$ . Hence and from the equality  $f''(x_0) = 0$  we have  $g''(x_0) = 0$ .

LEMMA 4. Let  $x_0 \in I$  and let  $\varphi_1, \varphi_2 \in F$  be such that  $\varphi_1 \neq \varphi_2$ ,  $\varphi_1(x_0) = \varphi_2(x_0)$  and  $\varphi_1'(x_0) = \varphi_2'(x_0)$ . Then  $\varphi_1(x) > \varphi_2(x)$  for  $x \in I \setminus \{x_0\}$  (or the reverse inequality holds).

P r o o f. It follows from Lemma 1 that  $\varphi_1(x) \neq \varphi_2(x)$  for  $x \neq x_0$ . Suppose that the statement does not hold. Hence either  $\varphi_1(x) > \varphi_2(x)$  for  $x \in (a, x_0)$  and  $\varphi_1(x) < \varphi_2(x)$  for  $x \in (x_0, b)$  or  $\varphi_1(x) < \varphi_2(x)$  for

$x \in (a, x_0)$  and  $\varphi_1(x) > \varphi_2(x)$  for  $x \in (x_0, b)$ . Let us consider the first case, the other is similar. Applying Lemma 3b) for  $f = \varphi_1$ ,  $g = \varphi_2$  and for  $f = \varphi_2$ ,  $g = \varphi_1$  we have  $\varphi_1''(x_0) \geq \varphi_2''(x_0)$  and  $\varphi_2''(x_0) \geq \varphi_1''(x_0)$ , respectively. Hence  $\varphi_1''(x_0) = \varphi_2''(x_0)$ . From H(ii) we get  $\varphi_1 = \varphi_2$ , a contradiction.

**LEMMA 5.** Let the assumptions and condition (B) of the Theorem be fulfilled. Then for every  $x_1, x_2$  such that  $a < x_1 < x_2 < b$  the inequality

$$\psi(x) < \bar{\varphi}(x) \quad \text{for } x \in (x_1, x_2)$$

holds, where  $\bar{\varphi} \in F$  is determined by conditions (4).

**P r o o f.** Let  $a < x_1 < x_2 < b$  and let  $\bar{\varphi}$  be determined by conditions (4). Let us assume that the statement is false. Then two cases are possible

a)  $\psi(x) \leq \bar{\varphi}(x)$  for all  $x \in (x_1, x_2)$  and

$$\psi(c) = \bar{\varphi}(c) \quad \text{for a } c \in (x_1, x_2);$$

b) there exists a  $c \in (x_1, x_2)$  such that  $\psi(c) > \bar{\varphi}(c)$ .

**Case a).** From Lemma 3a) we have  $\psi'(c) = \bar{\varphi}'(c)$ . Let us observe that  $\bar{\varphi}$  is just the function determined by (2) with  $x_1$  and  $x_2 = c$ . By (B) we get  $\psi(x) > \bar{\varphi}(x)$  for  $x \in (x_1, c)$ , contrary to a).

**Case b).** Let us consider the function  $\varphi_1$  determined by (2) with  $\bar{x}, c$  in place of those  $x_1, x_2$ , where  $\bar{x} = \sup \{ x \in [x_1, c) : \psi(x) = \bar{\varphi}(x) \}$ . By this definition  $\bar{x} \in [x_1, c)$  and

$$(5) \quad \psi(\bar{x}) = \bar{\varphi}(\bar{x}) = \varphi_1(\bar{x}), \quad \psi(x) > \bar{\varphi}(x) \quad \text{for } x \in (\bar{x}, c],$$

and from (B) we have

$$(6) \quad \psi(x) > \varphi_1(x) \quad \text{for } x \in (\bar{x}, b) \setminus \{c\}.$$

By (6) we have  $\bar{\varphi}(x_2) = \psi(x_2) > \varphi_1(x_2)$ , but

$\bar{\varphi}(c) < \psi(c) = \varphi_1(c)$ , therefore there exists a point  $d \in (c, x_2)$  such that  $\bar{\varphi}(d) = \varphi_1(d)$ . The values of functions  $\bar{\varphi}$ ,  $\varphi_1$  are equal at the points  $\bar{x}$  and  $d$  and those functions are not identically equal because  $\varphi_1(c) = \psi(c) > \bar{\varphi}(c)$ . By Lemma 2 we have  $\varphi_1(x) > \bar{\varphi}(x)$  for  $x \in (\bar{x}, d)$  and from (6) we get

$$(7) \quad \psi(x) > \varphi_1(x) > \bar{\varphi}(x) \quad \text{for } x \in (\bar{x}, c).$$

If  $\bar{x} = x_1$ , then  $\psi(\bar{x}) = \bar{\varphi}(\bar{x})$ ,  $\psi'(\bar{x}) = \bar{\varphi}'(\bar{x})$  and from

(7) we get  $\varphi_1'(\bar{x}) = \bar{\varphi}'(\bar{x})$ . Thus the mixed problem

$$\varphi(\bar{x}) = \psi(\bar{x}), \quad \varphi'(\bar{x}) = \psi'(\bar{x}), \quad \varphi(d) = \bar{\varphi}(d)$$

has two different solutions  $\bar{\varphi}$ ,  $\varphi_1$ , what is impossible.

Let  $\bar{x} > x_1$ . From (7)  $\varphi_1'(\bar{x}) \geq \bar{\varphi}'(\bar{x})$ . If  $\varphi_1'(\bar{x}) = \bar{\varphi}'(\bar{x})$  then we proceed as in the case  $\bar{x} = x_1$ . Let  $\varphi_1'(\bar{x}) > \bar{\varphi}'(\bar{x})$ .

Hence and from the equality  $\varphi_1(\bar{x}) = \bar{\varphi}(\bar{x})$  we get that

there is an  $l$  such that  $\varphi_1(x) < \bar{\varphi}(x)$  for  $x \in (l, \bar{x})$ .

From (B) we have  $\varphi_1(x) > \psi(x)$  for  $x \in (a, \bar{x})$ , in parti-

cular  $\varphi_1(x_1) > \psi(x_1) = \bar{\varphi}(x_1)$ . From the continuity of  $\varphi_1$

and  $\bar{\varphi}$  there is a  $p \in (x_1, \bar{x})$  such that  $\varphi_1(p) = \bar{\varphi}(p)$ .

Therefore  $\varphi_1 = \bar{\varphi}$  as they are members of  $F$  passing through the points  $(p, \varphi_1(p))$ ,  $(\bar{x}, \varphi_1(\bar{x}))$ ,  $(d, \varphi_1(d))$ .

**P r o o f o f T h e o r e m . (A)  $\implies$  (B).**

Let  $a < x_1 < x_2 < b$  and let  $\bar{\varphi}$  be determined by (2). We are going to prove the inequality

$$(8) \quad \psi(x) > \bar{\varphi}(x) \quad \text{for } x \in (x_1, x_2).$$

Let us assume that inequality (8) does not hold. Then two cases are possible

a)  $\psi(x) \gg \bar{\varphi}(x)$  for all  $x \in (x_1, x_2)$  and

$$\psi(c) = \bar{\varphi}(c) \quad \text{for a } c \in (x_1, x_2);$$

b) there exists a  $c \in (x_1, x_2)$  such that  $\psi(c) < \bar{\varphi}(c)$ .

Case a). Let us observe that  $\bar{\varphi}$  is just the function determined by conditions (1) with  $x_1, c, x_2$  in place of those  $x_1, x_2, x_3$ , therefore by (A) we have  $\psi(x) < \bar{\varphi}(x)$  for  $x \in (c, x_2)$ , contrary to a).

Case b). Let  $\bar{x} = \inf \{x \in (c, x_2] : \psi(x) = \bar{\varphi}(x)\}$ . Hence  $\bar{x} \in (c, x_2]$ ,  $\psi(\bar{x}) = \bar{\varphi}(\bar{x})$  and  $\psi(x) < \bar{\varphi}(x)$  for  $x \in [c, \bar{x})$ ,

If  $\bar{x} < x_2$ , then since  $\psi$  is strictly convex with respect to  $F$ , we have  $\psi(x) > \bar{\varphi}(x)$  for  $x \in (x_1, \bar{x})$  and  $\psi(x) < \bar{\varphi}(x)$  for  $x \in (\bar{x}, x_2)$ , because  $\bar{\varphi}(x_1) = \psi(x_1)$ ,  $\bar{\varphi}(\bar{x}) = \psi(\bar{x})$  and  $\bar{\varphi}(x_2) = \psi(x_2)$ . Hence, in particular,  $\psi(x) > \bar{\varphi}(x)$  for  $x \in [c, \bar{x})$ , a contradiction.

Let  $\bar{x} = x_2$  and let us consider the function  $\varphi_1$  determined by (1) with the points  $x_1, c, \bar{x}$ . From (A) we get the inequality  $\psi(x) < \varphi_1(x)$  for  $x \in (c, \bar{x})$  and just as in the proof of Lemma 4 (inequality (7)) we have

$\psi(x) < \varphi_1(x) < \bar{\varphi}(x)$  for  $x \in (c, \bar{x})$ . But  $\psi(\bar{x}) = \bar{\varphi}(\bar{x})$  and  $\psi'(\bar{x}) = \bar{\varphi}'(\bar{x})$ , therefore  $\bar{\varphi}'(\bar{x}) = \varphi_1'(\bar{x})$ . In this way we

obtain two different functions  $\bar{\varphi}, \varphi_1 \in F$  such that  $\bar{\varphi}(x_1) = \varphi_1(x_1)$ ,  $\bar{\varphi}(\bar{x}) = \varphi_1(\bar{x})$  and  $\bar{\varphi}'(\bar{x}) = \varphi_1'(\bar{x})$ , what by Lemma 1 is impossible. This concludes the proof of inequality (8).

The inequalities

$$\psi(x) < \bar{\psi}(x) \quad \text{for } x \in (a, x_1)$$

$$\psi(x) > \bar{\psi}(x) \quad \text{for } x \in (x_2, b)$$

follows from (8), (A) and from Remark 1.

$$(B) \implies (C).$$

Let  $x_0 \in I$  and let  $\bar{\psi}$  be determined by (3). First we are going to prove that

$$(9) \quad \psi(x) < \bar{\psi}(x) \quad \text{for } x \in (a, x_0).$$

Assume the contrary. Then either

$$\text{a) } \psi(x) \leq \bar{\psi}(x) \quad \text{for } x \in (a, x_0) \quad \text{and} \quad \psi(c) = \bar{\psi}(c) \\ \text{for a } c \in (a, x_0),$$

or

$$\text{b) there exists a } c \in (a, x_0) \text{ such that } \psi(c) > \bar{\psi}(c).$$

To disprove a) let us observe (Lemma 1) that  $\bar{\psi}$  is just the function determined by conditions (2) with  $x_1 = c$  and  $x_2 = x_0$ . By (B) we have  $\psi(x) > \bar{\psi}(x)$  for  $x \in (c, x_0)$ , a contradiction.

Case b). Let  $\psi_1$  be a function determined by (2) with  $x_1 = c$  and  $x_2 = x_0$ . From (B) we have

$$(10) \quad \psi(x) > \psi_1(x) \quad \text{for } x \in (c, x_0).$$

It follows from the definition of  $\psi_1$  that  $\psi_1(x_0) = \bar{\psi}(x_0)$ ,  $\psi_1'(x_0) = \bar{\psi}'(x_0)$  and  $\psi_1(c) = \psi(c) > \bar{\psi}(c)$ . Hence and from Lemma 4 we obtain the inequality

$$(11) \quad \psi_1(x) > \bar{\psi}(x) \quad \text{for } x \in (a, x_0).$$

By (10) and (11) we get

$$\psi(x) > \psi_1(x) > \bar{\psi}(x) \quad \text{for } x \in (c, x_0).$$

From the definition of  $\bar{\varphi}$  and from Lemma 3c) used for the functions  $f(x) = \psi(x) - \bar{\varphi}(x)$  and  $g(x) = \varphi_1(x) - \bar{\varphi}(x)$  we get  $\varphi_1''(x_0) = \bar{\varphi}''(x_0)$ , what contradicts H(ii).

Now we are going to prove that

$$\psi(x) > \bar{\varphi}(x) \quad \text{for } x \in (x_0, b).$$

Assume the contrary. Then two cases are possible

- a)  $\psi(x) \geq \bar{\varphi}(x)$  for  $x \in (x_0, b)$  and  $\psi(c) = \bar{\varphi}(c)$  for a  $c \in (x_0, b)$ ;
- b) there exists a  $c \in (x_0, b)$  such that  $\psi(c) < \bar{\varphi}(c)$ .

Case a). Let us observe (Lemma 1) that  $\bar{\varphi}$  is just the function determined by (4) with  $x_1 = x_0$  and  $x_2 = c$ .

From Lemma 5 we get  $\psi(x) < \bar{\varphi}(x)$  for  $x \in (x_0, c)$ , a contradiction.

Case b). Let  $\varphi_2$  be a function determined by (4) with  $x_1 = x_0$  and  $x_2 = c$ . By Lemma 5 we have  $\psi(x) < \varphi_2(x)$  for  $x \in (x_0, c)$ . As in the proof of (9) (Case b) we obtain  $\psi(x) < \varphi_2(x) < \bar{\varphi}(x)$  for  $x \in (x_0, c)$  and  $\varphi_2''(x_0) = \bar{\varphi}''(x_0)$ . In this way we get two different functions  $\varphi_2, \bar{\varphi} \in F$  such that  $\varphi_2^{(1)}(x_0) = \bar{\varphi}^{(1)}(x_0)$   $i = 0, 1, 2$ , what by H(ii) is impossible.

$$(C) \implies (D).$$

Let  $a < x_1 < x_2 < b$  and let  $\bar{\varphi}$  be determined by (4).

First we shall show that

$$(12) \quad \psi(x) < \bar{\varphi}(x) \quad \text{for } x \in (x_1, x_2).$$

Let us assume that inequality (12) does not hold.

Then either

a)  $\psi(x) \leq \bar{\psi}(x)$  for  $x \in (x_1, x_2)$  and  $\psi(c) = \bar{\psi}(c)$   
for a  $c \in (x_1, x_2)$

or

b) there exists a  $c \in (x_1, x_2)$  such that  $\psi(c) > \bar{\psi}(c)$ .

Case a). By Lemma 3a) we get  $\psi'(c) = \bar{\psi}'(c)$  and by Lemma 3b)  $\psi''(c) \leq \bar{\psi}''(c)$ . From (C) we obtain that the case  $\psi''(c) = \bar{\psi}''(c)$  cannot occur, therefore  $\psi''(c) < \bar{\psi}''(c)$ . Now let us consider the function  $\psi_1$  determined by (3) with  $x_0 = c$ ,  $\psi_1 \neq \bar{\psi}$  because  $\psi_1''(c) = \psi''(c) < \bar{\psi}''(c)$ . From (C) we have

$$(13) \quad \psi_1(x) > \psi(x) \quad \text{for } x \in (a, c)$$

and

$$(14) \quad \psi_1(x) < \psi(x) \quad \text{for } x \in (c, b).$$

From (14) we get  $\psi_1(x) < \bar{\psi}(x)$  for  $x \in (c, x_2)$  and from the definition of  $\psi_1$  and from Lemma 4 it follows that

$\psi_1(x) < \bar{\psi}(x)$  for  $x \in I \setminus \{c\}$ . Hence, in particular,

$\psi_1(x_1) < \bar{\psi}(x_1)$ , but from (13) we have  $\psi_1(x_1) > \psi(x_1) = \bar{\psi}(x_1)$ , a contradiction.

Case b). Put  $\bar{x} = \sup \{x \in [x_1, c) : \psi(x) = \bar{\psi}(x)\}$ . Thus  $\bar{x} \in [x_1, c)$  and  $\psi(x) > \bar{\psi}(x)$  for  $x \in (\bar{x}, c]$  and  $\psi(\bar{x}) = \bar{\psi}(\bar{x})$ . Hence  $\psi'(\bar{x}) \geq \bar{\psi}'(\bar{x})$ . Let  $\psi_2 \in F$  be determined by (3) with  $x_0 = \bar{x}$ .

If  $\psi'(\bar{x}) > \bar{\psi}'(\bar{x})$ , then  $\bar{x} > x_1$  and we proceed as in the proof of Lemma 5 (case b)  $\bar{x} > x_1$ ) and we get the contradiction with the condition H(iii).

Let  $\psi'(\bar{x}) = \bar{\varphi}'(\bar{x})$ , then by Lemma 3b) we get  $\psi''(\bar{x}) > \bar{\varphi}''(\bar{x})$  and it follows from (C) that  $\psi''(\bar{x}) \neq \bar{\varphi}''(\bar{x})$ , i.e.

$$(15) \quad \psi''(\bar{x}) > \bar{\varphi}''(\bar{x}).$$

By (C) we have  $\varphi_2(x) < \psi(x)$  for  $x \in (\bar{x}, b)$  and in particular

$$(16) \quad \varphi_2(x_2) < \psi(x_2) = \bar{\varphi}(x_2).$$

Lemma 4 and (16) yield  $\varphi_2(x) < \bar{\varphi}(x)$  for  $x \in I \setminus \{\bar{x}\}$ . Thus

$$(17) \quad \varphi_2''(\bar{x}) \leq \bar{\varphi}''(\bar{x}).$$

From (15) and from the definition of  $\varphi_2$  we have

$$\varphi_2''(\bar{x}) > \bar{\varphi}''(\bar{x}), \text{ what contradicts (17).}$$

Now we shall show that

$$\psi(x) < \bar{\varphi}(x) \quad x \in (a, x_1),$$

where  $\bar{\varphi}$  is determined by (4).

Let  $\varphi_3 \in \mathcal{F}$  be determined by (3) with  $x_0 = x_1$ . From (C) we get  $\psi(x) > \varphi_3(x)$  for  $x \in (x_1, b)$  and from (12)

$\varphi_3(x) < \bar{\varphi}(x)$  for  $x \in (x_1, x_2)$ . Hence and by Lemma 4 we obtain  $\varphi_3(x) < \bar{\varphi}(x)$  for  $x \in (a, x_1)$ , from (C)

$\psi(x) < \varphi_3(x)$  for  $x \in (a, x_1)$ . Thus  $\psi(x) < \bar{\varphi}(x)$  for  $x \in (a, x_1)$ .

The inequality

$$\psi(x) > \bar{\varphi}(x) \quad \text{for } x \in (x_2, b)$$

follows from (12), (A) and from lemmas 3 and 4.

$$(D) \implies (A).$$

Let  $a < x_1 < x_2 < x_3 < b$  and let  $\bar{\varphi}$  be determined by (1). We shall prove that

$$(18) \quad \psi(x) > \bar{\varphi}(x) \quad \text{for } x \in (x_1, x_2).$$

Again, let us assume that inequality (18) does not hold. We shall consider two cases

a)  $\psi(x) \geq \bar{\varphi}(x)$  for  $x \in (x_1, x_2)$  and  $\psi(c) = \bar{\varphi}(c)$   
for a  $c \in (x_1, x_2)$ ;

b) there exists a  $c \in (x_1, x_2)$  such that  $\psi(c) < \bar{\varphi}(c)$ .

Case a). By Lemma 3a) we have  $\psi'(c) = \bar{\varphi}'(c)$ . Thus  $\bar{\varphi}$  satisfies (4) with  $x_1 = c$  and  $x_2$ , so that, by (D), we get  $\psi(x) < \bar{\varphi}(x)$  for  $x \in (c, x_2)$ , contrary to the inequality in a).

Case b). Let  $\bar{x} = \sup \{ x \in [x_1, c) : \psi(x) = \bar{\varphi}(x) \}$ . By this definition  $\bar{x} \in [x_1, c)$ ,  $\psi(\bar{x}) = \bar{\varphi}(\bar{x})$  and  $\psi(x) < \bar{\varphi}(x)$  for  $x \in (\bar{x}, c)$ , whence  $\psi'(\bar{x}) \leq \bar{\varphi}'(\bar{x})$ . If we had  $\psi'(\bar{x}) = \bar{\varphi}'(\bar{x})$ , then  $\varphi$  would satisfy (4) with  $x_1 = \bar{x}$ ,  $x_2 = x_3$  and the first inequality of (D) would contradict (1). Therefore

$$(19) \quad \psi'(\bar{x}) < \bar{\varphi}'(\bar{x}).$$

Now let us consider the function  $\varphi_1$  determined by (4) with  $x_1 = \bar{x}$  and  $x_2$ . Since  $\varphi_1'(\bar{x}) = \psi'(\bar{x})$  and  $\varphi_1(\bar{x}) = \bar{\varphi}(\bar{x})$ , we see from (19) and from the continuity of  $\varphi_1$  and  $\bar{\varphi}$  that  $\varphi_1(x) < \bar{\varphi}(x)$  for  $x$  from a right neighbourhood of  $\bar{x}$ .

From (D) we have the inequalities

$$(20) \quad \psi(x) < \varphi_1(x) \quad \text{for } x \in (\bar{x}, x_2)$$

and  $\psi(x) > \varphi_1(x)$  for  $x \in (x_2, b)$ . The latter yields

$\psi(x_3) > \varphi_1(x_3)$ . Hence and from the equality  $\psi(x_3) = \bar{\varphi}(x_3)$  we have

$$(21) \quad \bar{\varphi}(x_3) > \varphi_1(x_3).$$

Applying Lemma 2 for  $\psi_1$  and  $\bar{\psi}$  with  $x_1$  replaced by  $\bar{x}$ , we get  $\psi_1(x) < \bar{\psi}(x)$  for  $x \in (\bar{x}, x_2)$  and  $\psi_1(x) > \bar{\psi}(x)$  for  $x \in (a, \bar{x}) \cup (x_2, b)$ , in particular  $\psi_1(x_3) > \bar{\psi}(x_3)$ , what contradicts (21).

The inequality

$$\psi(x) < \bar{\psi}(x) \quad \text{for } x \in (x_2, x_3)$$

follows from (18) and from (D).

**R e m a r k 2.** By a suitable change of inequalities that appear in the Theorem we get the conditions equivalent to the fact that  $\psi$  is convex, or concave or strictly concave with respect to  $F$ .
